ABSTRACT

This paper reviews the current extent of, research into, and future expectations for the use of online bibliographic retrieval systems by untrained end users rather than by trained search intermediaries. Six sections cover: (1) studies of direct end user searching, done primarily with students or persons in highly technical fields; (2) problems to be addressed before end user access can become common practice, including the variability of search procedures and the user's possible lack of computer, online searching, and information seeking experience; (3) suggested solutions to these problems, including standardization of online search procedures, training of end users, and the development of user-friendly system modifications; (4) methods and systems currently used to train novice online users, including TRAINER, DIATOM, and IIDA (Individualized Instruction for Data Access); (5) current research into user-friendly system modifications, with descriptions of VSS (Vocabulary Switching System), CONIT (COnnector for Networked Information Transfer), IIDA, TSW (The Searcher's Workbench), PaperChase, MICROsearch, CITE (Current Information Transfer in English), and OL'SAM (Online Search Assistance Machine); and (6) projections concerning the future direct use of computer information systems. A 54-item bibliography is provided as well as a 38-item annotated bibliography of ERIC publications and information on how to order ERIC documents. (ESR)

THE DIRECT USE OF ONLINE BIBLIOGRAPHIC INFORMATION SYSTEMS BY UNTRAINED END USERS: A REVIEW OF RESEARCH

The control of the establishment of the control of the establishment of

"An infinition of retrieval system is one in which a user in, via computer, three in interrogate a machine-readable database of documents or be ment representations" (25). Online bibliographic systems, analogous to in emechanized indexes, are access tools directing the user to appropriate sources by providing citations, and in many cases, short descriptions (i.e., abstracts) of documents. Bibliographic systems do not provide the user with the contents of documents as do knowledge-based (also called full-text or expert) systems. If ill-text is a major consideration in future value information provision, but beyond the scope of this paper.

End users are those who will actually be using the information, not necessarily the persons who conduct the search online. Intrained end users may be subject experts, but they may not have the familiarity, training and skills presently associated with searching and retrieving information from computerized systems. Currently, the <u>direct</u> use of online retrieval systems is primarily performed by trained search experts. End users supply questions and interact with professional online searchers who formulate strategies and then search appropriate online databases. It is the expert intermediary who directly uses the online system.

Many predict that this situation will change and that "end users' of information systems (library patrons, students, etc.) will input their requests and receive output without the assistance of a trained intermediary... (and that)...an important application problem for the 1980's will be the adaptation of on-line computing and microcomputing to the information tasks of everyday life" (37). The browser who is inclear as to exactly what he is seeking, the student working his or her way through a particular subject area, and the

PROBLEMS

Which the above resear and cates the potential for discombine searching, the actual use of online bibliographic data uses by untrained users a several discombined. There are serious problems to addressed before our discombines can become common printine.

Migor difficulties arise from the proliferation and variability of online systems and data bases, specifically the multiplicity and inherent complexities of a bess procedures, command languages, indexing vocabularies, data base structures, search and retrieval functions, and output formats. A user is presented with a choice of potentially appropriate data bases and systems, but each database to be accessed has unique sign-on procedures, differing command words and grammur, and a varying range of allowable search options. "With controlled vocabulary, free text, combinations of both, subject categories, and variations in indexing philosophy over the data bases,

A second to the constitution of the event period of expension the mean time of the constitution of the various languages, structures, and provide trained sols. TRAINER, and the training package developed at the longerate of Pittsburgh, provides for practice by potential users of DIALOG and SDG. Along with an economical office, TRAINER of this specific of dies to take learner the representations. TRAINER of this specific of dies to take learner the representations. TRAINER is intended to be used either independently on in conjunction with formal classroom a structure, the isomeoperated a strong case for using order instructional programs to many loskilled users as well as to extend the "population of knowledge one isers" of unline services (7).

The DIATOM similator developed at Syracise University by Robert Waldstein has the similar objective of providing online teaching opportunities and experience without the expense of access through commercial iddition (52). DIATOM affor a search system and user interface very close in operation to DIALOG and a choice of data bases. Although this allows inexperienced searchers to spend extensive time using a retrieval system similar to those presently available commercially, DIATOM does not lead or guide instruction.

Meadow's IIDA (Individualized Instruction for Data Access) project is committed to the objective of enabling "olid users of bibliographic information to perform their own searches under certain discumstances" (39, p.326). Operating as an intermediary between the mediager and the online system. IIDA has both online ussistance and pro-use training appointies.

contribe in ring a simplified form of computer-assisted instruction, interspersed with a consequences. Topics covered include basic sourceasts, idvanced commands, text searching, search strategy, daticage tescriptions, beginning and ending the search, and IIDA for risk 35, p.327-37. The role of the instructional mode is integrally text to the overall IIDA package rescribed in detail prioso), and innike TRAINER, does not include instruction in telegral invariants and gives procedures.

Stidles of the relative effectiveness of any pericular training Moderney have been generally a conclusive. In addition to the omputer-consted packages described above (see also filley (49)), methods range from written training aids such as those developed for SCORPIO, the Library of Congress retrieval system (4%), to a combination of instructional sessions, worksheets, and lab evergises (3, 4, 12, 17, 26). Each of these approaches has met with a degree of success; however, it is not possible to make definitive statements about the value of one vs. another. Even in a situation where training was minimal (Tietelbaum and Sewell's survey of pathologists and pharmacists), over half of the respondents felt their searching ability to be competent (48, p.300). It is questionable whether more specific investigation to determine those methods that are truly more effective (as well as economical) can ever yield conclusive results. For more discussion on education and training efforts, refer to Bourne and Robinson's comprehensive review through 1980 (3).

SYSTEM MODIFICATIONS

The alternative to raising the level of end user ability is to somehow make the system itself more capable and "user-friendly." In their work for the National Library of Medicine (NLM), Goldstein and Ford (16) utilized an "intelligent terminal" (a computer with a microprocessor physically incorporated into the terminal) to make the system more "user-cordial" rather than having the user "conform to rigid protocols and learn special codes." Selander pointed out that system designers need to consider (1) user objectives, (2) current procedures, (3) tutorial aids, (4) system organization, and (5) machine intelligence in order to improve system cordiality (43, p.66). The overall objective should be to provide users with a system which is

in the first of the second of

Relating that of a consisting scale, the differences of indexing chargonal harmonists and obtained to have a soft in the charge obtained by the control of the policy of an automated subject devised the V stabulars Switching System (VSS), an automated subject switching system "able to translate user requests into useful search queries across target fatibases with little user intervention" (32, p.397). Niehoff reports that while initial evaluation results for VSS were encouraging by the conflictive, they fit support the assections that no single data on this authoritatively sufficient, and agriduantly higher repull is possible when one searches helliple data bases.

Marcus and Reinties (2) also focused on the proble as generated by multiple and complex onable retrieval systems. They proposed a solution which involved the ancessing of online utilities and data bases through a computer interface (CONIT) designed to handle both access and vocabulary problems. The interface is ... a common system into which and from which requests and results are translated autoformatically as they flow between user and serving system. ... A user afte upting to retrieve information, when entering this right the access mechanism provided by the common interface, seen a single virtual system in which all the complexities of the different retrieval systems and databases are hiddent only a single, uniform, easy-to-use system is apparent" (28, p.288).

The CONIT system handles different existing, stand-alone online data base systems without modification and replaces existing, difficult-to-use heterogeneous interfaces with a simpler, easier-to-use interface. In addition to the controlled-vocabulary search mechanisms of existing systems, CONIT also provides a natural-language, keyword-stem approach for searching. This allows the searcher to enter any term (word or phrase in free-form English), not just those included in a special, restricted vocabulary. The system modifies the entry by using only key words from a phrase and word stems rather than full words. Natural language searching is one response to the problems associated with the multiplicity of vocabularies, structures, and search functions of individual data bases and retrieval systems.

That is a second of the second

The PON in sect 3 in her part of frees the problems associated with the green was attempted pring raste of to improve user that to the content of a content in the system acts as an "interior at assistant" or "hospital coach" boottoning and appraising the search, exactly and common is and responses, looking for errors or between acts as of problems.

Decayse each of the single IIDA cannot prescribe how a particular sear 1 th ad be a iduated. However, since it does have information about correct syntax, about searches in general, and what has been the history of the current search, IIDA can react by offering suggestions on how to proceed in the context of the error or problem encountered. IIDA employs a set of diagnostic procedures, and when a problem is detected can "(i) inform the user of the nature of the problem, (2) offer advice on what to do next, and (3) offer a remoder of what reference information is available concerning this specific problem" (30, p.327-330). In addition, the system has an extensive HELP facility allowing the user to request quick advice, a search sum cary, more detailed information, or the option of changing IIDA modes (e.g., from assistance back to instruction). IIDA curre itly runs on the MIT MULTICS computer system and CONIT software (described above); however, it doubt be adequately handled by a minico opinter soch as Digital's PDP 1.1 (29, p.58).

Preece and Williams (36) have proposed a microcomputer-based intelligent terminal able to offer uniform access to multiple data bases with many of the desirable features previously described. "The Searcher's Workbench" (TSW) is designed to make the user unaware of the operational differences among online systems and data bases (i.e., the differences are unseen or "transparent" to the user), offering instead a single, uniform front-end (the part of the online system with which the user interacts) for online searching. Central to TSW is the definition of a "model search system." User input is analyzed in terms of the pre-defined model and then altered to the specific

callying to linguistic the specific of the axer's, aterias, and attribute of constitude managers to be true are maralled by models atoms to the model. In a tartain use of its are incorporated into the model offering the user direct access to search-enhancing and tutorial aids.

ISW was call, designed from a user's perspective. Users are presented with a single, simplified system bolstered with a stance capabilities; however, experienced users are able to bypass the structured system and conduct standard boolean searching on nultiple data bases. Users are also afforded the advantages of to inh panel input. For most procedures, rather than entering commands and responses by toping on the keyboard, they are simply touch indicated areas of the screen.

To date only a prototype TSW (PTSW) has been built. This comprises a loose configuration of hurdware devices, not just one piece of equipment. A production-model TSW (with the same goal of "implementation of access to diverse search systems through user interaction with an ideal model search system") would be a single unit or a cluster of terminals sharing a central processor (35, p.404). Proceed and Williams also foresee the possibility of a TSW operational software package adaptable to many popular interacomputers using available commercially in the near fiture.

Similar to IIDA and TSW in providing online search assistance is PaperChase, mentioned earlier. PaperChase has the capability for monitoring the search in order to make recommendations for improvements, usually by suggesting (additional) search terms. Since the available database is a subset of the MEDLINE data base, the use of a MeSH term (i.e., a term from the controlled medical subject heading vocabulary) can greatly enhance chances for success. The program encourages the user to type whatever seems appropriate, removes blanks and punctuation, and attempts to match input to MeSH terms and rotated versions of MeSH terms. In this way the system presents alternative search terms which the user can utilize. PaperChase also provides online help facilities, sorted display (most recent items appearing first), and sorted output (listed in the order that journals are shelved in the hospital library) (19).

A project which also relies on a subset from the tapes of a large data base is MICROsearch, developed by Bruce Clark at the ERIC Cleuringhouse on Information Resources, Syracuse University (8). Directly aimed at the audience of non-professional searchers,

The problem of the problem of the Angle Terror with the risk fixe), and the problem of the problem of the Angle Terror with the risk fixe), and the problem of the problem

Let age this solution providing stand-alone databases on a small control of the system is the invited storage provided by the 5% inchestication. There is miscous to the best of ERIC required using many fiskettes, users were frust to be the failure to retrieve anything on tak after disk. One approal to overcome this has been the move to some it-related sets of disks rather than simply dividing them into sets chronologically. Another after upt to conpensate for the limited storage space is the RE-EXECUTE feature whereby the RX command allows for automatic "re-execution" of previously used search terms (along with associated logical operators) on multiple disks. As diskette storage supposity in a second as more sites acquire hard disk drives, the overall problem should diminish.

Current efforts involving MICRO-earch include working on the space problem, refining the programming, and making the system available if other inferocomputers. In addition, field testing uncovered two needs: (1) the ability to create local files that can be searched with MICRO-search, and (2) an interface designed to facilitate learning to search which can adapt a the user grows in sophistication (i.e., as the user is able to exercise more control, the interface does loss). The local files capability is already available and design of the interface is underway.

The promising research efforts described above have been aimed primarily at providing a means of educating and/or assisting the user in naximizing the benefit obtainable from existing boolean systems. Acknowledged, but not confronted, is the question of what would happen if the boolean mechanism itself were replaced. Salton (41, 42), can Rijsbergen (51), Sparck-Jones (45, 46), Oddy (33), Preece (35), Kraft (24), and others (2, 39, 40) have been investigating search

type system which does demonstrate the possibility of the income a search to the operational data has some National Library of Medicine's MEDLINE--is CITE (Correct Internation Transfer in English). Developed by Doszkock, CITE offers lateral language piery apability along with weighted and ranked output, role in a boodback, and automatic query modification.

Natural language allows the user to enter sour holtens a tree-form language, rather than being limited to a special command spillax detoscar? Verabolars. Does sent intations retrieved are weighted by the "number of query terms shared by a given natition and the relative frequency of such terms in the MEDLINE file? (11, p.135). The entries are displayed in decreasing order of importance as determined by the weighting. Through re-vance feedback, the CITE user is able to offer a judgement as to actual importance, thereby religing the search, since modifications of the search query are made by the system based upon the characteristics of the

^{*}Clustering refers to a mathematical process whereby documents are grouped together as members of clusters. Ventor spaces, a concept from linear algebra, can be used for representing distances (i.e., closeness) among documents in a collection. Weighting is the practice of assigning weights to search terms to indicate their importance. Probabilistic indexing uses a measure of term importance to indicate the likelihood that a term should be assigned to a given document. The probability measures can be used as term weights and documents can then be retrieved nink order according to the probability of relevance to a given ery (42, p.422). Relevance feedback takes user reactions to documents (relevance), algebra at large times them to the search mechanism in order to improve retrieval.

the control of the co

FUTURE DIRECTIONS

care, they ask and similar growth can be predicted in the direct use of exception ration systems. Meadow has projected the pattern of tevelopment in computer programming to online searching, stating that end users "will become like modern amateur programmers, able to handle routine problems on their own, needing the help of specialists when they get beyond the elementary level" (31, p.52). The problems associated with direct end use (i.e., the multiplicity and complexity of systems, databases, access and command procedures, indexing vocabilisties, database structures, search functions, and output formats; the mexperience of isers in online searching and information weeking may observed as ribed in this paper. Likewise, the

approximate the first construction of the first of the second training to the second construction of the second construction of the first second construction of the first second construction of the second const

In the lating a number of systems (database aspagement, full-text, all expert, as well as hibhographic) will be employed by end isets to ment rater nation needs. To this end, interaction must be the block of "iset-time (W"--a goal already a epted by many conserved with the development of these systems. Researchers in our matter regrey domistic earlings to build on the offers described the paper as well as to expand their concerns beyond belong uphic of the systems.

The experimental work with intelligent interfaces has shown the feasibility and offertiveness of itilizing a computer as intermediary. Research it issers (i.e., cognitive models, search strategy, and decry torinulation) and machines (e.g., artificial intelligence and memory dapabilities) is needed to provide a basis and gridans for development. Further design and testing of specific systems is warranted to fully explore the capabilities of intelligent terminals, alternative hardware/software combinations, the impact of changes in interface design, and the effectiveness of certain features with specific user groups.

Future offorts to make online systems are accessible to occasional users must take into account the potential for applying results from artificial intelligence research. "Artificial intelligence (XI) is a branch of computer science which attempts to develop programs to enable computer systems to communicate fluently, to explain why they have taken certain actions, to handle unforeseen situations, and to exhibit other similar signs of inteiligent behavior" (Sandewall; in 44, p.384). Application of AI techniques for pattern recognition, representation, problem solving, and learning can help in making system languages easy for the user to understand, and in creating systems which relieve users of unnecessary chores (44, p.385). While acknowledging the progress represented by IIDA and CITE, Smith makes a strong case for employing artificial intelligence techniques in these efforts and in future designs.

The control of the co

The constant is transfer to this vertical in experimental sections attern a straight of systems, and, and property to the should have any solving levels of supplictuation. One of there early ventures into this area, the brackly listitutes OLSAM (Ordine Search Assistance Machine) (59) to a torsion of rail, and no supplier-based, front-end processor related to the CONIT and IIDA procests. OLSAM offers a variety of assistance (e.g., auto logon, help paragraphs, prompting) and administrative teatures (e.g., a single command language, searches reported on disk, and administrative log) as a software package for the North Star Hommon II. Although the differences and changing nature of contrasystems have raised some problems, OLSAM demonstrates the rapidly of even merchal product and others can be expected to the land.

The macroimputer-based, self-contained system demonstrated by Clark's MicRosearch offers a locally controlled online capability that Social increase in appeal. Whether using downloaded subsets of large databases or locally created files, MicRosearch offers real online information opportunities for non-profession I searchers. System usefulness will grow with more widespread use of larger memory devices and increasing capacity of existing storage structures. The work on an adaptable interface, effective for isers with varying amounts of experience and sophistication, has widespread application in the development of systems and training of searchers.

The research efforts using an intelligent terminal to investigate alternatives to biologic or medified boolean search mechanisms (e.g.,

various research and to some experiences to the contract of the meson and Oddy, also ment for the election of the contract of the ability to test afternative mechanisms in the source source of the engine of finitive statements about performances.

Regaring the training of elements, stanes of various instructional approaches have four teach to be useful in improving performance. Online tutorials, manuals and handouts, formal instruction and workshops, and even just trial and error, all appear to be reasonable to impress. Although study in this area is likely to continue, it is doubtful whether definitive, comparitive results are possible.

And, finally, stidies of intrained end users must expand beyond undergraduate stidents, graduate stidents, and persons only in highly specialized areas. As database services expand to include more sources of interest to the general public, the full range of potential users must be taken into account. While journals have reported on the popular use of entine information services (mostly commercial information utilities, e.g., The Source, Dow Jones, Compuserve, BRS After Dark, DIALOG's Knowledge Index) by home computer enthusiasts, little has been done to formally analyze this group or other nore "general" direct users.

Even high school students are beginning to interact with online systems, e.g., the availability of the Guidance Information Service (GIS) in many secondary schools. Wozny (54) reported on a study by Drott and Mancall where high school students used online bibliographic searching and conventional searching to obtain information for an independent research assignment. Results were surprising in that the online searches resulted in few references in the students' bibliographies, although it appeared that online searching played a key role in meeting the objectives of (1) making students aware of the diversity of institutions and sources that supply information, and (2) providing new opportunities for assisting students in developing search strategies. More investigation into the abilities, attitudes, and approaches of this group of users is needed.

In the future, there will be a myriad of computer and information systems available to a range of users. The research, development, and design projects described in this paper are just a beginning. The goal for information and library professionals remains the same: to put patrons in contact with the information or sources of information

they need as quickly and easily as possible. Online systems directly accessible is pon-professional ad users will be important tools in their off to attain this goal.

Measurement and Improvement of Subject Specialists Performance Searching Chemical Abstracts Online as Available on SDC Search Systems.

Copeland, Richard F.; And Others

Bethune-Cookman Coll., Daytona Beach, FL.

Jun 1980 142p.

EDRS Price - MF01/PC06 Plus Postage.

The first phase of a project to design a prompting system to help semi-experienced end users to search Chemical Abstracts online, this study focused on the differences and similarities in the search approaches used by experienced users and those with less expertise. Four online searches on topics solicited from chemistry professors in small colleges—the target group for the prompting system—vere conducted by each of the 12 participants, who were divided into three groups on the basis of their prior experience. Each participant received a packet of materials introducing the project, searching, and search aids, and SDC's chemistry manual, and a slide/tape presentation was shown at the time of the test. It was found that,

This report describes project activities designed to identify the critical issues and problems in designing and developing library bibliographic retrieval systems for direct patron use. The results of a survey, an insues analysis paper, and a working session indicate four priority areas for study and action, user and use characteristics, interface characteristics, the library environment, and the computing environment. Recommendations made by the working session participants highlight the consensus of their concerns--the analysis of user requirements and behavior, the monitoring of existing nublic access systems, the relopment of materials for cost manaand the development of distributed computing and system $\pi_{\rm c}$

EDRS Price - MF01/PC03 Plus Postage.

Controlled experiments were conducted with an enhanced experimental intermediary system, CONIT (Consector for Networked Information Transfer), to test how effective subsystem could be in assisting end users in online searching of medical and biomedical literature. A total of 16 end users, none of whom had previously operated CONIT or any of the four bibliographic retrieval systems used in the study, performed searches on 20 different topics with no assistance other than that provided by CONIT itself (except to recover from machine and software problems). The same topics were then searched by human expert intermediaries (librarians) with the end users present. Sometimes CONIT and sometimes the human expert were clearly superior in terms of such parameters as recall and search time. In general, however, end users searching alone with CONIT achieved somewhat higher online recall at the expense of

Research in networking of heterogeneo. Tractive bibliographic retrieval systems is being conducted which centers on the concept of a virtual retrieval system. Such a virtual system would be created through a translating computer interface that would provide access to the different retrieval statems and data bases in a uniform and convenient way, even for the inexperienced user. An experimental interface, called CONIT, has been built to test the virtual system concept. Initial evaluation of CONIT, which connects four retrieval systems, suggests that the virtual system approach could be cost effective. Particular attention was focused on the requirements for a common command language, ease of use, and message interpretation and protocols in a networked interface. (Author/JY)

The realization that the facilities available for the retrieval of scientific and technical information were being underutilized resulted in a project being undertaken by the Drexel University School of Library and Information Science to develop a computer intermediary capable of assisting users of scientific and technical information in the performance of online bibliographic searches. Individualized Instruction for Data Access (IIDA), the computer system developed during the project, operates in an instructional and an assistance mode, and can be used to train users to perform online searches or to aid users in search performance. The system employs a set of diagnostics which alert users to the strategic and syntactic errors they make during the search process. When IIDA was operational, a number of evaluations of the system were made, first using undergraduate computer science majors and experienced online searchers, then library science faculty and graduate students and undergraduate engineering students, and finally engineers at the Exxon Research facility in Florham Park, New Jersey. The evaluation studies indicated that individuals who had never done online searching were able, using IIDA, to do searches which produced satisfactory results. Detailed accounts of the design of the system, system operations, and the methodology of the evaluation studies are given, and the project bibliography is included. (JL)
